Chapter 10. Binomial Option Pricing: Basic Concepts

$\$ 10.1 A one-period Binomial tree

- § 10.2 Constructing a Binomial tree
- § 10.3 Two or more binomial periods
- § 10.4 Put options
- § 10.5 American options
- § 10.6 Options on other assets
- § 10.7 Problems

Binomial option pricing

The binomial option pricing model or Cox-Ross-Rubinstein pricing model assumes that

the price of the underlying asset follows a binomial distribution,

that is,

the asset price in each period can move only up or down by a specified amount.

The binomial option pricing model enables us to determine the price of an option, given the characteristics of the stock or other underlying asset. Example 10.1-1 Consider an European call option on the stock of XYZ, with a \$40 strike price and one year expiration. XYZ does not pay dividends and its current price is \$41.

Assume that, in a year, the price can be either \$60 or \$30.

Can one determine the call premium?

(Let the continuously compounded risk free interest rate be 8%.)

Law of one price

Positions that have the same payoff should have the same cost!

Two portfolios (positions)

- ▶ Portfolio A: Buy one 40-strike call option.
- ▶ Portfolio B: Buy $\Delta \in (0, 1)$ share of stock and borrow **B** at the risk-free rate.

These two positions should have the same cost.

Solution. The cost for Portfolio B at day zero is

$$\Delta \times S_0 - B.$$

and its payoff at expiration is

$$\begin{aligned} \Delta \times 30 - \mathbf{B} \times \mathbf{e}^{0.08} & \text{if the stock price is } 30 \\ \Delta \times 60 - \mathbf{B} \times \mathbf{e}^{0.08} & \text{if the stock price is } 60 \end{aligned}$$

On the other hand, the payoff for Portfolio A should be

$$\begin{cases} 0 & \text{if the stock price is } 30 \\ (60 - 40) & \text{if the stock price is } 60 \end{cases}$$

By equating the two payoffs, one obtains that

$$\begin{cases} \Delta \times 30 - \mathbf{B} \times \mathbf{e}^{0.08} = 0\\ \Delta \times 60 - \mathbf{B} \times \mathbf{e}^{0.08} = 60 - 40\end{cases}$$

Solution. Hence,

$$B = 20 \times e^{-0.08}$$
 and $\Delta = 2/3$.

Finally, since the cost of Portfolio A has to be equal to that of Portfolio B, we find the cost of Portfolio A:

$$\Delta imes oldsymbol{S}_0 - oldsymbol{B} = rac{2}{3}oldsymbol{S}_0 - 20 imes oldsymbol{e}^{-0.08}.$$

If we plug in $S_0 =$ \$41, we have

B = \$18.462 and the cost is \$8.871.

 \square

More generally, suppose the stock change its value over a period of time h as

Portfolio A

Payoff	d imes S	$u \times S$
Option	0	u imes S - K
Total	$C_d = 0$	$C_u = u \cdot S - K$

Portfolio B

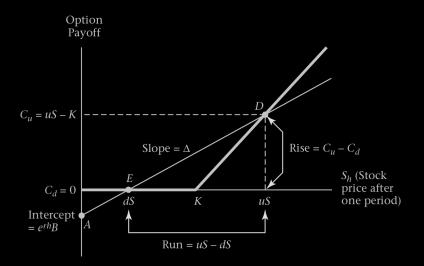

Payoff	d imes S	u imes S
Δ share	$\Delta \cdot \boldsymbol{d} \cdot \boldsymbol{S} \cdot \boldsymbol{e}^{\delta h}$	$\Delta \cdot \boldsymbol{u} \cdot \boldsymbol{S} \cdot \boldsymbol{e}^{\delta h}$
B bond	Be ^{rh}	Be ^{rh}
Total	$\Delta \cdot \boldsymbol{d} \cdot \boldsymbol{S} \cdot \boldsymbol{e}^{\delta h} + \boldsymbol{B} \boldsymbol{e}^{rh}$	$\Delta \cdot \boldsymbol{u} \cdot \boldsymbol{S} \cdot \boldsymbol{e}^{\delta h} + \boldsymbol{B} \boldsymbol{e}^{rh}$

For two unknowns: Δ and B, solve:

 $\begin{cases} \Delta dSe^{\delta h} + Be^{rh} = C_d \\ \Delta uSe^{\delta h} + Be^{rh} = C_u \end{cases}$

Set S_h be either dS or uS and C_h be either C_u or C_d . Plot S_h (x-axis) versus C_h (y-axis).

 $\Delta \mathbf{S}_{h} \mathbf{e}^{\delta h} + \mathbf{B} \mathbf{e}^{\mathbf{r} h} = \mathbf{C}_{h}$

$$\Delta = e^{-\delta h} \frac{C_h - C_d}{S(u - d)} \quad \text{and} \quad B = e^{-th} \frac{uC_d - dC_u}{u - d}$$

$$\Delta S + B = e^{-rh} \left(C_u \underbrace{\frac{e^{(r-\delta)h} - d}{u-d}}_{:=\rho^*} + C_d \underbrace{\frac{u-e^{(r-\delta)h}}{u-d}}_{:=1-\rho^*} \right)$$

 p^* the **risk-neutral probability** of an increase in the stock price.

Arbitraging a mispriced option

Example 10.1-2 Find arbitrage opportunities in Example 10.1-1 with

- ► the option price being overpriced with \$9.00;
- ► the option price being underpriced with \$8.25,

instead of the risk-neutral pricing \$8.871.

Solution. One can buy the synthetic option which cost \$8.25 and sell the real one by earning \$9.00. Hence, the present value of the profit is

9 - 88.871 = 0.129.
